The variation in c_t can be expressed by the equation $C_4 + C_1 + C_2$ (A) (ao) From this it appears that the capacity C_2 between grid and filament is important in increasing the apparent input capacity. The maximum increase (for $i_p r_p$) is $k C_2$. It is of interest $k R$ to note that the quantity-- is, under the assumed fre r_p t-tp quency conditions, the ratio of the voltage across R_p to the input F_{io} . 3.-- Variation of input characteristics with resistance load in the plate circuit voltage E_g and hence determines the voltage amplification per stage of a resistance coupled amplifier. Thus the apparent input capacity can become a number of times greater than the actual capacities between the tube electrodes, and since the apparent input resistance can also become very high, the dissipation of power in the input circuit of the tube may be considerable, even when the grid is negative with respect to the filament. When the frequency is so high that the terms containing t_{c2} become important, these resistance and capacity effects become less marked. For very high frequencies $r_g=0$ This latter is the capacity of C_2 and C_1 , in series and paralleled by C_3 , --i. e., the capacity between filament and grid with...
